2018 GRAIN SORGHUM CROP REVIEW

Statewide Growing Conditions

The 2018 sorghum season presented an overall fair weather pattern, with more than 50% of the crop condition rated as good and excellent at harvest. Wet conditions in the spring delayed planting in specific locations; however, overall planting progress was near or slightly delayed from last year but close to the average as relative to the last 5-yr average (2013-2017). Early season (June) warm temperatures sped up the vegetative progress, compensating for the delay caused by the early wet conditions or delayed planting.

Sorghum heading was concentrated during early-August (50% state-level) and early-September (close to 100% state-level). Conditions during vegetative-phase and pollination remained wet with near-average temperatures, favoring the pollination time and early-reproductive period.

Hail was a problem across the state. There were 526 reports of large hail throughout the season. Of those events, 223 were reported in May. Hail has a larger impact when it occurs later during the grain filling period (September and early October), when the plant depends on the leaves, potentially affecting seed set (both seed number and weight).

As related to the precipitation conditions, all divisions averaged above normal for the period of April 1 through October 15 (Table 1). The greatest departure was in the southwest, where the divisional average was 23.87 inches or 154% of normal. Unfortunately, the rains weren't evenly distributed across the region or across the season. At the St. John station, rainfall was below normal until mid-August. A wet end to August was followed by even wetter conditions in September and October, which complicated harvest.

Temperatures weren't as much of a factor. The warmest readings were seen in mid-July, with the highest read of 112°F reported on July 21 at Ashland, Clark County.

The biggest factor was the rapid switch from much colder than average temperatures to warmer temperatures. State-wide average temperatures in April were the coldest since 1895, while state-wide average temperatures in June were the warmest on record. The first autumn freezes were near average, with Colby dropping to 27°F on the 14th of October, and Concordia reaching 27°F on the 15th. As related to grain filling, this period started with good or above-average moisture content and moved to saturated conditions as the crop was approaching harvest time. Temperatures also went from near normal to below normal average temperatures, delaying maturity. By the end of October, sorghum harvest was only 32% complete, reflecting the delay due to weather challenges (e.g., precipitations, snow).

The sugarcane aphid (*Melanaphis sacchari*) appeared in more concentrated areas (small-pockets) impacting sorghum primarily from the mid-vegetative to late reproductive stages. Still fewer reports were documented during 2018 compared to the 2016 growing season, but with a similar geographical distribution relative to 2017 season.

Harvest progress for sorghum across the state was delayed, primarily occurring during late October and late November. Overall, harvest progress is similar relative to last year but 10% behind the 5-year average.

Despite the previously mentioned challenges, U.S. Department of Agriculture forecasted in November a sorghum yield of 86 bushels per acre for the state of Kansas for the 2018 season, above the 82 bushels per acre from the 2017 season. Production at the state-level increased by 27 million bushels relative to last year's production (Ignacio A. Ciampitti, Kansas State University Cropping Systems Specialist, and Mary Knapp, Kansas State University Climatologist).

Table 1. 2018 temperatures by crop production district

| Division | Extreme Tmax (°F) | Date | Avg Tmax (°F) | Avg Tmin (°F) | Avg Tmean (°F) | Extreme Tmin (°F) | Date |

| Southwest | 112 | 21-Jul | 83.0 | 54.8 | 68.9 | 14 | 7-Apr |
| South central | 103 | 1-Sep | 82.1 | 57.6 | 69.8 | 13 | 7-Apr |
| Southeast | 103 | 20-Jul | 80.7 | 59.1 | 69.9 | 17 | 16-Apr |

Diseases

The 2018 Kansas sorghum crop was healthier than any in recent memory. Sooty stripe levels were high in some south-central Kansas fields, but generally less than in 2017. Late season rains caused an increase in head molds, but overall, incidence was relatively low.

The most significant disease in 2018 as usual, was Fusarium stalk rot. Fusarium thrives in wet spring, followed by a dry summer, and then more rain as harvest approaches, which is what occurred in many areas of the state in 2018. However, reports of late season lodging were few. (Doug Jardine, Kansas State University Department of Plant Pathology)

Insects

The hot and dry weather from May-August was conducive to chinch bug development, which occurred in large numbers. Chinch bug feeding, coupled with adverse weather conditions, caused considerable early lodging and continued through the soft dough stage, which significantly reduced yields in many areas around the state.

Then "headworms", a combination of fall armyworms and corn earworms, started attacking the heads that were between flowering and soft dough, reducing yields if not treated.

Sugarcane aphids were continually migrating into the state from late July through early September. Fortunately, aphid natural enemies- i.e. parasitic wasps, lady beetles, green lacewings, syrphid flies, etc.- were plentiful and kept sugarcane aphid populations under control.

Adverse weather, coupled with insect infestations from the seedling to the soft dough stage, resulted in considerably smaller kernels, "blasted" heads, and reduced yields throughout much of the state. (Holly Davis and Jeff Whitworth, Kansas State University Department of Entomology.)

2018 PERFORMANCE TESTS

Objectives and Procedures

Grain Sorghum Performance Tests, conducted annually by the Kansas Agricultural Experiment Station, provide farmers, extension workers, and seed industry personnel with unbiased agronomic information on many of the grain sorghum hybrids marketed in the state. Because entry selection and location are voluntary, not all hybrids grown in the state are included in tests, and the same group of hybrids is not grown at all test locations.

A summary of growing-season weather data is given in individual test discussions. These data are from the nearest weather-reporting station and often are supplemented with information from the test site. Precipitation graphs include cumulative lines for 2018 from April to October. General trends in precipitation are readily observed in the graphs.

Explanatory information precedes data summaries for each test. Tables 3 through 18 contain results from the individual performance tests. Hybrids are listed in order of increasing days to half bloom when that information is available, so hybrids of similar maturity appear together.

As with individual test results, small differences should not be overemphasized. Relative ranking and large differences are better indicators of performance.

Three or four plots (replications) of each hybrid were grown in a randomized complete block design at each location. Each harvested plot consisted of two rows trimmed to a specific length ranging from 20 to 30 feet at the different locations.

Grain yields are reported as bushels per acre of shelled grain (56 lb/bu) adjusted to a moisture content of 12.5%. Yields also are presented as a percentage of test average to speed recognition of highest-yielding hybrids. Hybrids yielding more than 100% of the test average year after year merit consideration. Adaptation to individual farms for appropriate maturity, stalk strength, and other factors should also be considered.

Relative maturity is measured in terms of both number of days from planting to half bloom and grain moisture at harvest. Maturity can be critical when considering a sorghum hybrid for a specific cropping system.

Small differences in yield or other characteristics should not be overemphasized. Least significant differences (LSD) are shown at the bottom of each table. Unless two entries differ by at least the LSD shown, little confidence can be placed in one being superior to the other.

The coefficient of variability (CV) can be used to estimate the degree of confidence one can have in published data from replicated tests. In this testing program, a CV of less than 10% generally indicates reliable, uniform data, whereas a CV of 10 to 15% is not uncommon and usually indicates that data are acceptable for the rough performance comparisons desired from these tests. Tests with a CV greater than 15% still may be useful, especially in situations with low yields.

Information provided by entrants:

GC = grain color: bronze, cream, red, yellow, white

EC = endosperm color: white, yellow, hetero-yellow

PC = plant color: purple, tan

Mat. = relative maturity: early, medium, late

Days = days to half bloom

G-bug = resistance to specific greenbug biotypes: C, E, I, K, etc.

SCA = resistance to Sugarcane Aphids

Excerpts from the University Research Policy Agreement with Cooperating Seed Companies

Permission is hereby given to Kansas State University (KSU) to test varieties and/or hybrids designated on the attached entry forms in the manner indicated in the test announcements. I certify that seed submitted for testing is a true sample of the seed being offered for sale.

I understand that all results from Kansas Crop Performance Tests belong to the University and the public and shall be controlled by the University so as to produce the greatest benefit to the public. Performance data may be used in the following ways: 1) Tables may be reproduced in their entirety provided the source is referenced and data are not manipulated or reinterpreted; 2) Advertising statements by an individual company about the performance of its entries may be made as long as they are accurate statements about the data as published, with no reference to other companies' names or cultivars. In both cases, the following must be included with the reprint or ad citing the appropriate publication number and title: "See the official Kansas State University Agricultural Experiment Station and Cooperative Extension Service Report of Progress 1147, '2018 Kansas Performance Tests with Grain Sorghum Hybrids,' or the Kansas Crop Performance Test website, www.agronomy.k-state.edu/services/crop-performance-tests/index.html, for details."
