# 2001 KANSAS WHEAT PERFORMANCE TEST

## INTRODUCTION

This publication presents results from the 2000-2001 Kansas Winter Wheat Performance Tests and other information related to winter wheat variety performance. The information included in the report is intended to assist wheat producers in the variety selection process. The first section summarizes statewide growing conditions and harvest information for the entire 2001 Kansas wheat crop. Statewide acreage distribution of leading Kansas varieties and a summary of important agronomic and quality traits for these varieties follow. The third section presents procedures and results for the 2001 Kansas Winter Wheat Performance Tests.

## 2001 CROP CONDITIONS

### Weather Conditions

The 2000-2001 wheat season had some interesting weather that contributed to a less than ideal growing season. The first challenge was the extremely hot and dry planting period. Rainfall ranged from 3/4" to 2 1/5" below the 30-year average in September (Figure 1). This was on top of extremely hot and dry conditions in August.

Figure 1. September 2000 precipitation by crop reporting district.

Figure 2. October and November temperature departures from normal.

Although the dry conditions moderated at the end of October, temperatures took a very quick nose-dive (Figure 2). October average temperatures ranged 1 - 3 °F above normal. In contrast, November average temperature ranged from 5 to almost 8 °F below normal. This meant the wheat had very little time for growth and tillering before entering dormancy.

Winter conditions, unlike recent years, were fairly close to normal. There were periods of snow cover, favorable moisture, and very little sub-zero weather.

Spring conditions continued to be fairly normal. This meant periods of cool, wet weather broken by short periods of extremely warm conditions. The western third of the state tended toward warmer and drier conditions than the rest of the state.

Cool, wet conditions in early June allowed for an extended grain fill period. Excessive rainfall was a particular problem in the northeastern division. The Seasonal (October-June) total precipitation was above normal in all divisions, but this did not totally offset the earlier unfavorable conditions.

(From Mary Knapp, KSU State Climatologist).

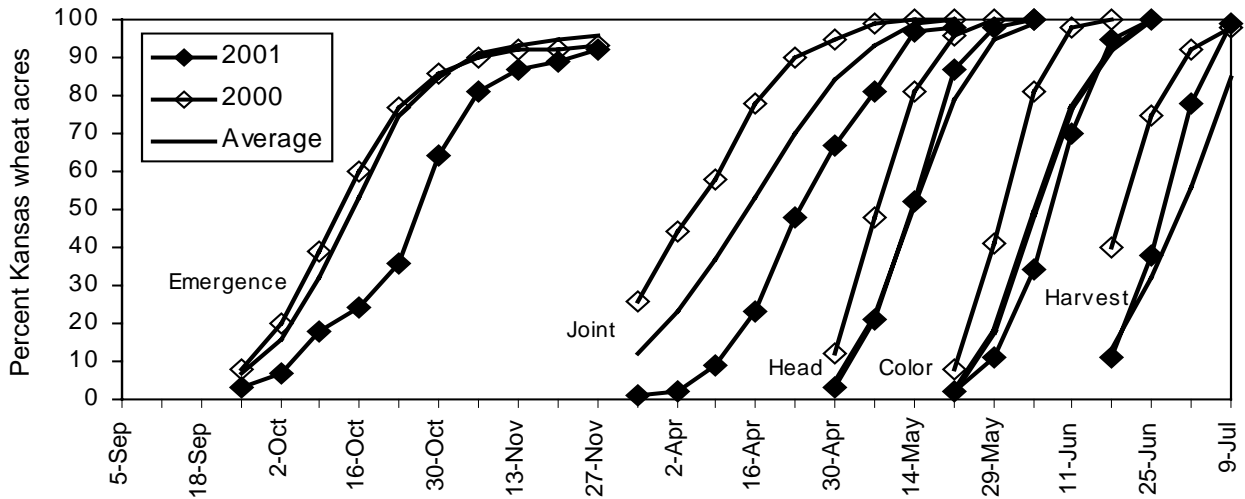

Figure 3. Statewide development of the 2000-2001 winter wheat crop.

### Crop Development

The 2001 wheat crop lagged far behind last year at almost every stage of development (Figure 3). Dry soils delayed seeding and emergence across much of the state. November brought much-needed precipitation, but cold temperatures slowed emergence and limited fall growth. In the spring, many of the poorest fields were plowed and replanted to summer crops. The wheat was slow to break dormancy in the spring. Jointing lagged 3-4 weeks behind last year and 2 weeks behind the 5-year average. Heading did not lag as much as jointing and was comparable to the average. Adequate rainfall and mild temperatures allowed the crop to fill the grain well. Although the rate of harvest was behind

that of last year, it actually outstripped the 5-year average.

Only about 50% of the crop started out in good to excellent condition (Figure 4). The condition of the crop generally declined from there until mid-May when over 75% was rated as fair or worse. The crop rebounded in response to the mild weather in spring and early summer and ended up with over 30% in good or excellent condition.

Soil moisture was short or very short on 99% of the acres in mid-September (Figure 5). The moisture situation finally improved in November when snow and rain accompanied cold temperatures. Winter and spring precipitation recharged soil moisture so that only 2-3% of the

Figure 4. Condition of Kansas winter wheat crop, 2000-2001.

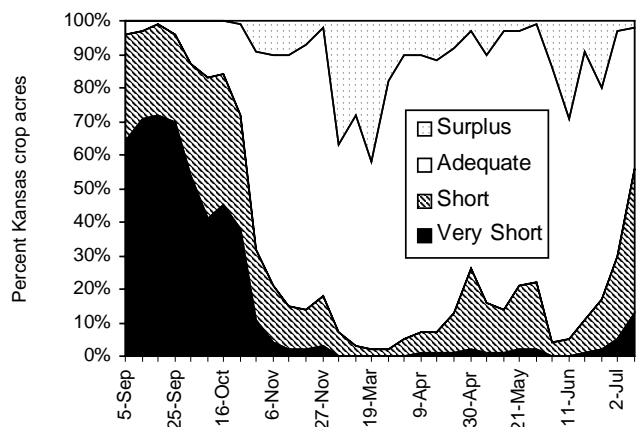

Figure 5. Statewide status of topsoil moisture, 2000-2001.

acres was ranked as short or very short of moisture by mid-March. Soils dried out somewhat in April and May, but rainfall was generally adequate for grain filling. After some early June rainfall, soil moisture declined until the completion of harvest.

(From *Crop-Weather* reports, Kansas Agricultural Statistics, Topeka).

## Diseases

The hot, dry summer of 2000 greatly reduced survival of volunteer wheat. This affected wheat streak mosaic virus and leaf rust, which survive on volunteer wheat. Dry conditions in the fall slowed planting progress, which probably further reduced fall disease problems. Rains eventually came to some areas, but then cold weather set in. Stands were very variable.

Winter conditions were cold and snowy and leaves were killed back to the ground in most fields. This was expected to reduce survival of diseases like leaf rust and powdery mildew that require green leaves. Surprisingly, no snow mold was reported and winter injury was uncommon.

In March and April, disease levels were unusually low. Spindle streak mosaic virus and soilborne mosaic virus were below average, but some new locations for these diseases were reported in western areas that received fall rains. Tan spot started strong in many continuous wheat fields and eventually became the second most important foliar disease in 2001. In many cases it seemed to spread into rotated fields. Speckled leaf blotch was active in a few fields. Wheat streak mosaic virus was generally rare, although there were a few hot spots. Powdery mildew and barley yellow dwarf were hard to find. Leaf rust was essentially absent.

Wheat stripe rust was first reported in southern Kansas on May 2 at Hutchinson on the mid-canopy leaves of variety 2137. Almost every plant had at least one stripe rust infection. Since it wasn't on the flag leaf, spores must have arrived prior to flag leaf emergence, which occurred during the last week of April. During the week of May 7, reports of stripe rust on middle leaves were coming from between Dodge City and McPherson and from south of Highway 56 to the Oklahoma border. By May 14, lesions were appearing on flag leaves. The varieties 2137, Hondo, Kalvesta, Lakin, Niobrara, Oro Blanco,

Platte, Prairie Red, TAM 107, TAM 110, Trego, and Venango were most often found to have a serious problem with stripe rust.

Unusually warm weather from May 14-17 was expected to inhibit further development of the epidemic. Stripe rust lesions on most varieties began to dry and turn brownish. In some cases, only a brown necrotic stripe was produced with no new pustules. Even when the rust was inhibited, flag leaf damage was often severe from the brown necrotic stripe reaction. By May 18, stripe rust had nearly defoliated susceptible varieties at the late milk stage across a wide area, mostly south of Highway 56.

On May 19, a cool, wet period began that lasted three weeks. On May 23, we began to hear reports of serious stripe rust north of I-70. By May 29, reports came from as far east as Seneca, as far west as Goodland, and as far north as Belleville. The epidemic north of I-70 was probably due to spores moving up from south central Kansas in a second wave of migration.

Losses due to stripe rust were documented in fungicide test plots. In southwest Kansas, losses sometimes exceeded 50% on susceptible varieties. In south central and north central Kansas, losses on 2137 ranged up to 20%. These losses were somewhat mitigated by cool weather which helped grain filling.

(From Robert Bowden, K-State Extension Plant Pathologist).

## Insects

Insect pests caused relatively little statewide damage to the 2001 wheat crop. Army cutworm moths were active in Kiowa County in early October. Fall armyworm was causing problems in early-planted fields in southwest Kansas by this time. Several fields in southwest Kansas were treated for this pest. Little insect activity was noted in early spring. Low numbers of flea beetles were found in western Kansas in early May. Armyworm moths were numerous in May and June, but the wheat matured fast enough to escape significant damage from this pest.

(From Kansas Department of Agriculture Cooperative Economic Insect Reports).

## Harvest Statistics

The Kansas Agricultural Statistics' July 11 estimate of the 2001 crop was 327.6 million bushels harvested from 8.4 million acres. This continues the 4-year decline in total production since the 1997 crop of close to 500 million bushels (Figure 6). This estimate was up 15% from the June forecast but down 6% from last year's production. The statewide yield average of 39 bushels per acre was up 5 bushels from the June prediction and 2 bushels above last year's final average.

(From July 11, 2001 *CROPS* report, Kansas Agricultural Statistics, Topeka).

## WHEAT VARIETIES GROWN IN KANSAS

### Acreage Distribution

The leading wheat varieties planted in Kansas are reported in Figures 7 and 8 and in Table 1. The top five varieties occupied 70.3% of the state's seeded acreage in 2001.

The top 10 varieties for each crop-reporting district are presented in Figure 7. In the western districts, 2137 and TAM 110 acreages increased. Acreages of Jagger, TAM 107, Ike, and Larned acreages were steady or dropped slightly. TAM

Figure 6. Historical Kansas winter wheat production.

107, the acreage leader for many years, ranked as low as the third variety in two of the three western districts. Blends maintained or increased their share of the acreage in the southwest and west central districts, but dropped in the northwest district.

Jagger and 2137 were still the most popular varieties in the central districts. However, blends ranked second in the north central district with 21% of the acreage. Karl/Karl 92 continue to occupy a significant portion of the acreage, especially in the north central district. The acreage of 2163 continues to drop in this region.

2137, Jagger, and Karl/Karl 92 were the most prevalent varieties in eastern Kansas once again. Jagger tended to dominate in the southeast with 50% of the acreage, but 2137 was the leading

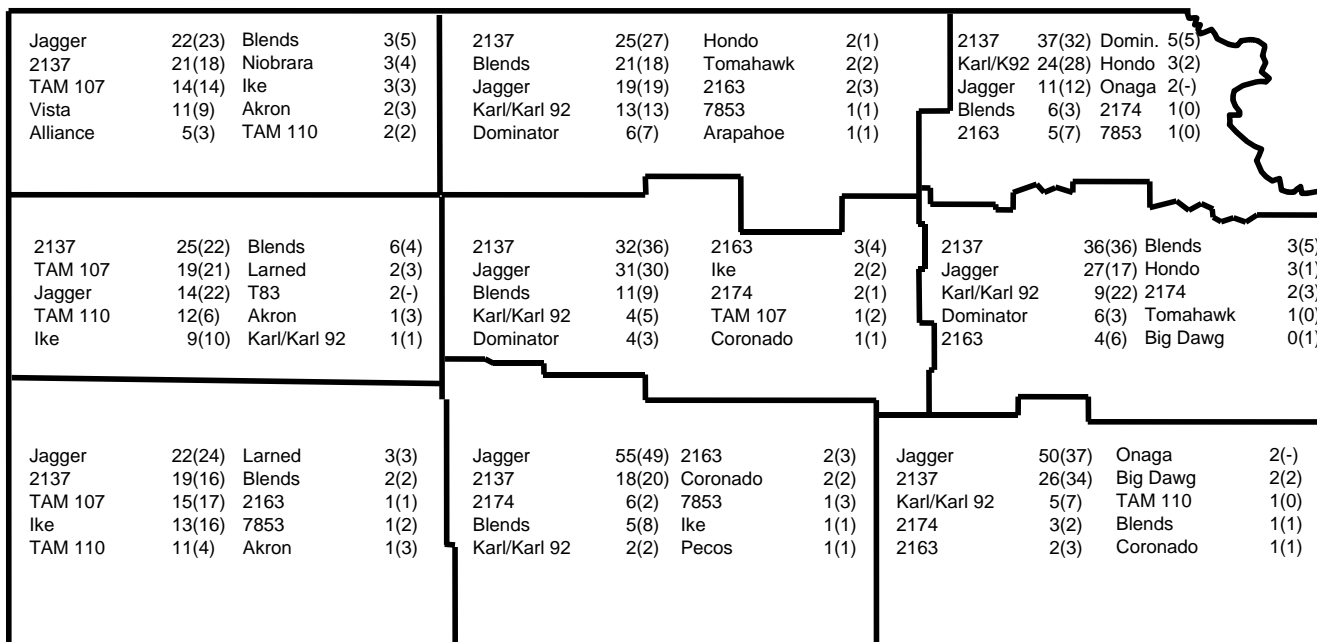

Figure 7. Leading wheat varieties in Kansas, presented as percent of seeded acreage by crop reporting district for 2000 and 2001 (2000 in parentheses). From Kansas Agricultural Statistics, Topeka.

variety in the northeast and east central districts. Onaga appeared in the top ten of the northeast and southeast districts for the first time.

Figure 8 illustrates the historical statewide distribution of the top 10 varieties in 2001. These varieties occupied 80.7% of the planted wheat acres in 2001. Jagger and 2137 together accounted for 58.1% of the 2001 acres. The percentage of acres occupied by Karl 92, 2163, and TAM 107, the predominant varieties for most of the 1990s, continued to decline at 10.6% in 2001. The remaining 5 varieties in the top 10 accounted for 12% of 2001 wheat acres. Ike was popular in the mid to late 1990s, but has declined in recent years. The acreage of Coronado has been relatively steady for the past 3 years. 2174, TAM 110, and Dominator are relatively new varieties with increasing acreages. (From February 12, 2001, *Wheat Variety* report, Kansas Agricultural Statistics, Topeka).

### Agronomic Characteristics

Comparative ratings for important agronomic traits, pest resistance, and milling and baking quality are listed in Table 1. Varieties are included in this table if they appear in the annual *Wheat Variety* survey report from Kansas Agricultural Statistics. Disease and insect ratings are from the annual report, *Wheat Variety Disease and Insect Ratings* by Robert L. Bowden and H. Leroy Brooks. Agronomic ratings are from

wheat breeders, extension specialists, and researchers. Ratings for a given trait in this table are experts' best estimates of the relative performance of the varieties based on information and observations over several seasons and from numerous sources. The ratings are updated annually to account for changes in performance that occur over time and to adjust for the changes in ranking that arise with the continued additions of new varieties.

### New Variety Descriptions

Brief descriptions of new public entries in the performance tests are included below. These descriptions are abstracted from release notices or other material provided by releasing agencies.

**Intrada** is the first hard white winter wheat variety released by the Oklahoma Agricultural Experiment Station. It is of medium late maturity and is intermediate in timing of first hollow stem stage. Test weight has been outstanding and grain yields have been competitive in Oklahoma tests. Baking evaluations for Intrada have been good to excellent.

Intrada is resistant to soilborne mosaic virus and stem rust, moderately resistant to leaf rust, moderately susceptible to tan spot and powdery mildew. It is susceptible to Russian wheat aphid, greenbug, and Hessian fly and has intermediate tolerance to acid soils.

Figure 8. Historical acreage distribution of top 10 varieties in 2001. From Kansas Agricultural Statistics, Topeka.

<sup>1</sup> Varieties and % seeded acreage from the Feb. 12, 2001, Wheat Variety survey, KS Ag. Statistics, Topeka, KS.

<sup>2</sup> Most ratings are experts' best estimate based on information and observations from many sources.

Agronomic information by Joe Martin, Hays, and Allen Fritz, Jim Shroyer, Ray Lamond, Kraig Roozeboom KSU Agronomy.

<sup>3</sup> Summary of crop performance test results from recent years.

<sup>4</sup> Ratings compiled by P.J. McCluskey are based on data from the KSU Department of Grain Science and Industry, the U.S. Grain Marketing and Production Research Center, and inputs from the milling and baking industries. See annual update of "Milling & Bread-baking Qualities of Hard Winter Wheat Varieties" for more information.

EX = Exceptional; large kernels; high protein content; very good milling, mixing, and commercial bread-baking.

AC = Acceptable; milling and baking attributes acceptable but not outstanding for all properties, may have minor defects.

LD = Less Desirable; one or more serious quality defects.

-- = Inadequate information or conflicting data.

\*Strong blending wheat; needed for blending with weaker wheats, may not be suitable alone for bread flour.

Scale: 1=Most resistant/tolerant  
9=Least resistant/tolerant

<sup>5</sup> Disease and insect resistance ratings provided by R.L. Bowden and W.W. Bockus, KSU Plant Pathology; and Leroy Brooks, KSU Entomology.

More complete and final ratings in addition to descriptions of disease and insect pests are available in "Wheat Variety Disease and Insect Ratings 2001" by Robert L. Bowden and H. Leroy Brooks.

Intrada is susceptible to pre-harvest sprouting and should not be grown in central and eastern Kansas as a result. Lodging may occur under conditions of high straw production or under irrigation. (Release notice from Oklahoma Agricultural Experiment Station).

**Lakin** hard white winter wheat was released by the Kansas Agricultural Experiment Station in August of 2000. It has performed best in southwest Kansas in both dryland and irrigated tests. Lakin is susceptible to leaf rust and has very little sprouting tolerance, thus it should not be considered for production in central or eastern Kansas. Lakin is unique in that it is the first white wheat released by K-State that has outstanding noodle quality along with above-average bread quality.

Lakin is of medium maturity, has good winterhardiness, and is intermediate in shattering resistance. It is moderately resistant to stem rust and wheat streak mosaic virus. It is resistant to soilborne mosaic virus but is susceptible to leaf rust and Hessian fly. (Release notice from Kansas Agricultural Experiment Station).

**Stanton** hard red winter wheat was released by the Kansas Agricultural Experiment Station in 2000. It was developed at the KSU Agricultural Research Center at Hays to address potential damage from Russian wheat aphid. Stanton derives resistance to that pest from PI222350. In the absence of Russian wheat aphid in western Kansas, Stanton has performed as well as or better than the best red wheat varieties and better than the currently available Russian wheat aphid resistant varieties.

Stanton is medium late in maturity, has white chaff, and is a tall semidwarf with good straw strength. Its winterhardiness is equal to Scout and it is non-shattering. Milling and baking characteristics are good. Stanton is moderately resistant to wheat streak mosaic virus and Hessian fly, resistant to leaf and stem rust, and susceptible to soilborne mosaic virus and barley yellow dwarf mosaic virus. (Release notice from Kansas Agricultural Experiment Station).

## PERFORMANCE TEST RESULTS

### Objectives

To help Kansas growers select wheat varieties

suitable for their area and conditions, the Kansas Agricultural Experiment Station annually compares both new and currently grown varieties and hybrids in the state's major crop-producing areas. The objective is to provide Kansas growers with unbiased performance information on varieties available in the state.

### Varieties Included in Tests

Parentage and origin of public varieties included in the 2001 performance tests are listed below.

Public varieties are selected for inclusion in the tests based on several criteria. Most represent new or established varieties with potential for successful use in Kansas. Some are included as long-term checks for use in environment or maturity comparisons. Others are entered at the request of the originating institution.

Privately developed varieties are entered into the Kansas Wheat Performance Tests by their originators or marketers. Entry is voluntary. Entrants choose both the entries and test sites and pay a fee for each entry-location to help defray test expenses. The program is similar to those for corn, sorghum, soybean, and alfalfa.

The 2001 private entrants and entries are listed in Table 3. Seven entrants provided a total of 18 varieties for testing at locations of their choice. Public and private entries were grown together at random in the same tests. Growers interested in more detailed descriptions of private entries should contact the entrants directly (see addresses and telephone numbers in Table 3 or consult the Kansas Crop Improvement Certified Seed Directory).

Table 12 describes the characteristics of seed submitted for testing. Seed quality, including such factors as size, purity, and germination, can be important in determining the performance of a variety. Wheat seed used for entries in the Kansas Crop Performance Tests is prepared professionally and usually meets or exceeds Kansas Crop Improvement Certification standards. Performance of a given variety or hybrid comparable to that obtained in these tests is best assured under similar environmental and

cultural conditions and with the use of certified or professionally prepared seed.

### Environmental Factors Affecting Individual Tests

Locations of test sites are shown on the map on the front cover. Four locations had to be abandoned because of environmental factors. Environmental factors should be considered when examining the remaining results as well. Several locations were subjected to unusual levels of stripe rust, significantly affecting test results. Site descriptions and management practices for each site are summarized in Table 4. Location codes in parentheses after each location name are used as column headers in the data tables.

### EAST

**Brown County (BR), Cornbelt Experiment Field, Powhattan:** This test was planted after corn in adequate moisture. All plots established good stands and exhibited very good yield potential. In spite of the fact that the nursery was planted on corn ground, very little Fusarium head blight was observed.

**Riley County (RL), Ashland Research Farm, Manhattan:** This test was planted in adequate moisture and had very good stands going into winter resulting in very little winterkill. Soil moisture was adequate to surplus throughout the growing season. Susceptible lines showed severe symptoms of soilborne mosaic virus in late March and early April. Moderate levels of stripe rust infection were observed, and leaf rust

<sup>1</sup> Seed weight of 2001 entries ranged from 24 to 44 grams/1000 kernels, averaging 32 grams/1000 kernels (see Table 12).

developed late in the growing season, but did not greatly reduce yields. Heavy rains in the month before harvest caused significant lodging.

**Franklin County (FR), East Central Experiment Field, Ottawa:** Favorable planting conditions resulted in good stands. Diseases caused less damage than typical for this location. However, leaf rust was present along with a trace of stripe rust.

**Labette County (LB), Southeast Agricultural Research Center, Parsons:** Dry weather in early fall followed by extremely wet weather delayed planting until mid-November. The wheat did not emerge until January. Cool spring weather slowed early growth, but the wheat was developing rapidly by early April. Leaf diseases were minimal.

#### NORTH CENTRAL

**Republic County (RP), North Central Experiment Field, Belleville:** Extremely dry conditions in early fall caused the test to be planted into dry soil. The wheat emerged when rains fell in late October. Good stands were obtained, but some stand was lost to winterkill. Early spring was cooler than normal with significant snowfalls in late February and early March. Cool, wet conditions in May provided very good grain filling conditions. Some stripe rust symptoms were observed in susceptible varieties.

**Smith County (SM), Farmer's field, Smith Center:** Adequate moisture at planting resulted in good stand establishment in mid-October. Spring weather was cool and wet. Grain filling conditions were favorable.

#### SOUTH CENTRAL

**Harvey County (HV), Harvey County Experiment Field, Hesston:** Wheat planting was delayed by extremely dry soil conditions. Heavy rainfall occurred within the first week after planting. Stand establishment was generally good, but cold temperatures in November greatly limited wheat development before winter dormancy. Winter precipitation was somewhat above normal in January, well above average in February, but below normal during the other winter months. Mean temperatures were sharply below normal in November and December and, to a lesser extent, colder than usual in February and March. Final wheat stands were somewhat less

than desirable in a few varieties. May temperatures were near normal, but the other spring months were cooler than usual. The spring period was dryer than usual, except for June. Favorable temperatures and moisture substantially benefited grain filling. Moderate soilborne mosaic symptoms occurred in late March and early April, significantly affecting subsequent growth and yield of some varieties. Stripe rust began to appear in early May, ultimately affecting the yield and test weight of susceptible varieties. No insects of significance were observed. Rain during the harvest period reduced test weight.

**Reno County (RN), South Central Experiment Field, Hutchinson:** Extremely dry fall conditions were mitigated by nearly an inch of rain 5 days before planting. Cool, dry conditions characterized the winter months, resulting in little wheat growth. Spring conditions were not favorable until mid to late May when the weather became wet and cool. These conditions continued through June, allowing good grain filling. A heavy rain just before harvest may have lowered test weights. Stripe rust lowered yields and test weights of susceptible varieties.

**Stafford County, dryland (SD), Sandyland Experiment Field, St. John:** Extremely dry, unfavorable planting conditions were followed by an early, harsh winter. Stripe rust was present on susceptible varieties. All these factors combined to make yields so variable that the test had to be abandoned.

**Sumner County (SU), Max Kolarik farm, Caldwell:** Heavy rains soon after planting caused severe crusting that prevented adequate stand establishment. As a result the test was abandoned.

#### WEST

**Ellis County (EL), KSU Agricultural Research Center, Hays:** A mid-October planting had very irregular stands because of non-uniform seedbed moisture. Early November rains did not improve stands appreciably, thus a second planting was attempted. Cold weather set in and delayed emergence until spring. The late-emerged stands were also poor and variable so the test was abandoned.

**Thomas County, dryland (TD), Northwest Research-Extension Center, Colby:** Good stands were established in all plots. Snow cover on the coldest winter days prevented winter kill. Cool temperatures and beneficial rains slowed early development until June, which was hot and dry. Stripe rust and minimal leaf rust were observed.

**Greeley County, dryland (GD), Southwest Research-Extension Center, Tribune:** Soil moisture was marginal at planting. Early spring conditions were dry, but the grain filling period was favorable. Susceptible varieties exhibited stripe rust symptoms.

**Finney County, dryland (FD), Southwest Research-Extension Center, Garden City:** Dry conditions at planting did not appear favorable, but all entries emerged. Most tillers of the more tender varieties (i.e. Newton, Heyne, and Culver) were killed during the winter. These later retillered with spring rains and below normal temperatures through the first week of June. Hot conditions in late June prematurely killed many of the late-maturing, retillered varieties. Stripe rust was severe on many varieties. Leaf rust also was noted.

#### IRRIGATED

**Stafford County, irrigated (SI), Sandyland Experiment Field, St. John:** See description for dryland test.

**Thomas County, irrigated (TI), Northwest Research-Extension Center, Colby:** See description for dryland test.

**Finney County, irrigated (FI) Southwest Research-Extension Center, Garden City:** Sprinkler irrigation in the fall facilitated good seeding establishment. The harsh winter thinned stands to some extent. May rains provided good grain filling conditions. Stripe rust symptoms were severe on susceptible varieties. Some leaf rust also was noted.

**Stevens County, irrigated (SV) Kramer Seed Farms, Hugoton:** This nursery was planted following corn and looked good from planting on. Good stands were obtained and the crop was well established going into winter. This nursery had very high yield potential throughout the growing season. The primary production constraint was a very heavy infection of stripe

rust. The resistant lines (i.e. Heyne, Betty, Karl 92, Jagger) did very well, but the susceptible varieties suffered yield losses of 60% or more due to the disease. Test weights of susceptible varieties also were reduced.

#### Test Results and Variety Characterization

Results from Kansas tests are presented in Tables 5 through 13. The information in these tables is derived from replicated varietal comparisons at several sites representing various wheat-producing areas of the state.

Characteristics of specific 2001 entries can best be determined by examining Figures 9-12, Table 1, and data in Tables 5 through 13 for the relative performance of new varieties or hybrids of interest compared to those the grower is currently planting. Yields are reported in Table 5a-d as bushels per acre (60 pounds per bushel) adjusted to a moisture content of 13%, where moistures were reported at harvest. In Table 6a-d, bushel yields are converted to yields as percentages of the test averages to speed recognition of highest yielding entries (more than 100%, the test average). The excellent performances of several of the entries are highlighted in these tables.

Growers should examine Table 7a-d to check the performance of entries over several years at locations closest to their farms. These tables present yields averaged over 2, 3, and 4 years. One-year or one-location results can be misleading because of the possibility of unusual weather conditions. This year especially, the unusually severe outbreak of stripe rust caused otherwise excellent varieties to perform poorly at some locations.

Additional agronomic characteristics are presented in Table 8a-d (test weights); Table 9a-d (relative heading dates); Table 10a-d (heights); Table 11 (disease and lodging notes); Table 12 (planted seed characteristics, coleoptile lengths, and Hessian fly ratings); and Table 13 (protein). Minimal shattering occurred in the tests in 2001.

At the bottom of each table is the LSD (least significant difference) for each column of replicated data. The use of the LSD is intended to reduce the chance of overemphasizing small differences in yield or other characteristics. Small variations in soil structure, fertility, water-holding characteristics, and other test-site characteristics can cause considerable yield variation among

plots of the same variety grown only a short distance apart.

Another statistical parameter is the coefficient of variation (CV) shown at the bottom of most columns. This figure, if properly interpreted, can be used to estimate the degree of confidence one may have in the data presented. In this testing program, CV's below 10% generally indicate reliable, uniform data, whereas CV's from 11% to 15% usually indicate less desirable but generally useful data for the rough performance comparisons desired from these tests.

### **Coleoptile Measurements**

Coleoptile length is a primary factor in determining the relative ability of a variety to emerge from deep planting. We have no evidence that coleoptile length plays a significant role in a variety's ability to emerge through a crust or compacted soil. However, long coleoptiles elongate faster than short coleoptiles, thereby sometimes escaping crusting problems as the result of quicker emergence.

Coleoptile length measurements will predict the relative ability of a cultivar to emerge from deep plantings through noncrusted soil. The actual planting depth for a variety is not limited to its coleoptile length. Once the coleoptile has reached its maximum length, the primary leaf breaks through the coleoptile and has the ability to move through an additional 2 to 3 inches of dry, noncompacted soil. Recent tests demonstrated that if a coleoptile elongated to 3.75 inches, the plant still had an 80% chance of emerging from a 6-inch planting depth. Emergence decreased to 40% for 2.5-inch coleoptiles and 20% for 2.0-inch coleoptiles.

Maximum coleoptile elongation of a variety is influenced heavily by soil temperature. As soil temperature increases from 65° F to 85° F, the coleoptile lengths of all varieties are reduced about 30%. As soil temperature decreases from 65° F, coleoptile lengths of the standard height varieties Larned and Eagle change very little, but the coleoptiles of semidwarf varieties TAM 107, Karl 92, and TAM 200 actually increase in length. At 53° F, the coleoptile lengths of TAM 107, Karl 92, and TAM 200 are equal to that of Eagle, and at 40° F, they are equal to that of Larned. If a producer is faced with deep planting because of dry soil late in the planting season, choice of

variety will have minimal effects on stand establishment. The same can be said for plantings made during our optimum planting times when soil temperature is already below 65° F. Plantings made in the latter part of August or early September when soil temperature is high will be the most vulnerable to poor emergence because of coleoptile length. If plantings have to be made deeper than 3.5 inches when soil temperature is high, it is advisable to use a variety that has a long coleoptile.

Coleoptile ratings reported in Table 12 are based on measurements at 75° F, which is the average soil temperature in western Kansas on Sept 1 at the 4-inch depth. Varieties with a rating of 8 had average coleoptile lengths of 2.4±.2 inches, whereas those rated 3 averaged 4.2±.2 inches. For one variety to be significantly different from another, the ratings must differ by at least 2 points.

### **Graphical Performance Summaries**

Figures 9-12 summarize the performance of each variety standardized to the average of two check varieties: Jagger and 2137. These were the most popular varieties in 2001 with 58% of the total wheat acreage.

The number of direct comparisons of a given variety with the check varieties has a bearing on the confidence one can place in the performance of that variety. The number beside each bar shows the number of years that variety was compared to the check varieties. In general, the greater the number of years that a variety has been tested, the greater confidence one can put in comparisons of that variety with the checks.

Symbols beside each bar indicate if a given variety was significantly greater (+) or lower (-) than the average of the check varieties. As with individual test results, small differences should not be overemphasized. Rather, relative ranking and large differences are better indicators of varietal performance.

Most disease ratings by Bob Bowden, Ext. Plant Pathologist; 1 = best, least disease reaction, 9 = poorest, most disease reaction. Single-location ratings should be interpreted with care. A number of ratings from many locations should be used to develop a more complete picture of disease and/or lodging reaction.

<sup>1</sup>Bob Bowden - 5/9/01 and 5/18/01, rated on 1-9 scale.

<sup>3</sup>SB = Soilborne mosaic virus - 3/21/01

<sup>2</sup>Curtis Thompson - 6/6/01, rating based on % of flag leaf infected.

<sup>4</sup>BB = Bacterial blight - 5/18/01

<sup>1</sup> Coleoptile length measured at 75 degrees F, which is the average soil temperature at 4" in western Kansas on September 1. Coleoptile rating of 3 is long and is equal to about 4.2", a rating of 8 is short and is equal to about 2.4". See discussion of coleoptile length on page 13. Ratings provided by T. Joe Martin, Kansas State University Agricultural Research Center - Hays.

<sup>2</sup> Hessian fly ratings by E. Parker, USDA; S = majority of plants susceptible, H = mixture of susceptible and resistant plants (heterogenous), R = majority of plants resistant. Tested with the Great Plains Hessian fly.

## Protein Content

Samples of grain from each variety harvested from Kansas Wheat Performance Tests are submitted annually for analysis of protein content, kernel hardness, and kernel weight and other tests. Screening for protein and other analyses are conducted by the staff at the U.S. Grain Marketing and Production Research Center in Manhattan, Kansas. Because of the time requirement for obtaining analyses, protein results presented below are for the previous year's tests.

Excerpts from the UNIVERSITY RESEARCH POLICY AGREEMENT  
WITH COOPERATING SEED COMPANIES\*

Permission is hereby given to Kansas State University to test varieties and/or hybrids designated on the attached entry forms in the manner indicated in the test announcements. I certify that seed submitted for testing is a true sample of the seed being offered for sale.

I understand that all results from Kansas Crop Performance Tests belong to the University and the public and shall be controlled by the University so as to produce the greatest benefit to the public. Performance data may be used in the following ways: 1) Tables may be reproduced in their entirety provided the source is referenced and data are not manipulated or reinterpreted; 2) Advertising statements by an individual company about the performance of its entries may be made as long as they are accurate statements about the data as published, with no reference to other companies' names or cultivars. In both cases, the following must be included with the reprint or ad citing the appropriate publication number and title: "See the official Kansas State University Agricultural Experiment Station and Cooperative Extension Service Report of Progress 869 '2000 Kansas Performance Tests with Soybean Varieties', or the Kansas Crop Performance Test website, <http://www.ksu.edu/kscpt>, for details. Endorsement or recommendation by Kansas State University is not implied."
