Subsurface drip irrigation (SDI) systems are feasible for some field crops and field arrangements using current levels of technology. Sprinkler irrigation systems have an economic advantage over SDI systems for the typical case where full-size center pivots can be used. However, center pivots lose important economies of scale as fixed investment costs are concentrated onto smaller acreages. Thus, the cost advantage for a center pivot system diminishes as field size is reduced.

This analysis assumes an existing flood-irrigated field with an existing well or water supply that is centrally located at the edge of the field. This flood-irrigation system is to be converted to either a center pivot or SDI system. The well is fully depreciated, but not in need of replacement.

Investment cost estimates for alternative irrigation systems and estimated crop budgets for irrigated corn and summer fallow wheat in western Kansas are used to project annual profitability for the alternative irrigation and cropping systems. The objective is to compare center pivot and SDI system costs and net returns per acre for several field sizes.

Field Investment Costs

Six field sizes were considered, starting with a standard quarter section (160 acres) on which a standard sized (125 acre) center pivot could be installed. The center pivot size was reduced in 25 acre increments from 125 acres down to 25 acres. The corresponding SDI field is assumed to be fully irrigated, whereas the center pivot field is assumed to have a combination of irrigated acres under the irrigated circle and nonirrigated acres on the center pivot corners. The exception is in the last comparison, which assumes a typically shaped 80-acre field (a quarter section split into two equal rectangular parts) on which a standard sized center pivot could "windshield wipe" a semicircle of 64 acres, leaving 16 acres in dryland wheat-fallow rotation.
Investment costs and acreages used to compare the profitability of these two alternative irrigated cropping systems are shown in Table 1.
Irrigation system investment costs were estimated using information from private industry and Kansas State University. In this analysis, the system life is projected to be 20 years for the center pivot and 10 years for the SDI system. Additionally, all the components of each irrigation system are assumed to have no salvage values at the ends of their projected lives.

Regular annual repair and maintenance expenses are assumed for each system. Per-acre investment cost for center pivots increase as field size decreases in comparison to more stable SDI per-acre investment costs.

Figure 1 graphically illustrates the proportional cost reduction of a SDI system as compared to the less-adjustable cost structure of a center pivot. For example, as field size decreases by 50 percent, the SDI system cost also decreases by approximately 50 percent. In comparison, as field size decreases by 50 percent, the center pivot system cost is about 80 percent of the full sized system.

Subsurface drip irrigation (SDI) systems are feasible for some field crops and field arrangements using current levels of technology. Sprinkler irrigation systems have an economic advantage over SDI systems for the typical case where full-size center pivots can be used. However, center pivots lose important economies of scale as fixed investment costs are concentrated onto smaller acreages. Thus, the cost advantage for a center pivot system diminishes as field size is reduced.

This analysis assumes an existing flood-irrigated field with an existing well or water supply that is centrally located at the edge of the field. This flood-irrigation system is to be converted to either a center pivot or SDI system. The well is fully depreciated, but not in need of replacement.

Investment cost estimates for alternative irrigation systems and estimated crop budgets for irrigated corn and summer fallow wheat in western Kansas are used to project annual profitability for the alternative irrigation and cropping systems. The objective is to compare center pivot and SDI system costs and net returns per acre for several field sizes.

Field Investment Costs

Six field sizes were considered, starting with a standard quarter section (160 acres) on which a standard sized (125 acre) center pivot could be installed. The center pivot size was reduced in 25 acre increments from 125 acres down to 25 acres. The corresponding SDI field is assumed to be fully irrigated, whereas the center pivot field is assumed to have a combination of irrigated acres under the irrigated circle and nonirrigated acres on the center pivot corners. The exception is in the last comparison, which assumes a typically shaped 80-acre field (a quarter section split into two equal rectangular parts) on which a standard sized center pivot could "windshield wipe" a semicircle of 64 acres, leaving 16 acres in dryland wheat-fallow rotation.

Investment costs and acreages used to compare the profitability of these two alternative irrigated cropping systems are shown in Table 1.

Irrigation system investment costs were estimated using information from private industry and Kansas State University. In this analysis, the system life is projected to be 20 years for the center pivot and 10 years for the SDI system. Additionally, all the components of each irrigation system are assumed to have no salvage values at the ends of their projected lives.

Regular annual repair and maintenance expenses are assumed for each system. Per-acre investment cost for center pivots increase as field size decreases in comparison to more stable SDI per-acre investment costs.

Figure 1 graphically illustrates the proportional cost reduction of a SDI system as compared to the less-adjustable cost structure of a center pivot. For example, as field size decreases by 50 percent, the SDI system cost also decreases by approximately 50 percent. In comparison, as field size decreases by 50 percent, the center pivot system cost is about 80 percent of the full sized system.

Profitability Analysis

Partial budgeting was used to compare the profitability of the alternative irrigation and cropping systems. Unlike a whole-farm budget, a partial budget does not indicate whether the entire operation is profitable, but only if one enterprise or investment has a net returns advantage over another.

Partial budgeting may not recognize all costs to the whole farm. For example, management of newly installed SDI systems may take more time than for the more familiar center pivot systems. The extra time is taken from other farm enterprises, which could affect their production efficiency and profitability. This is a SDI cost factor not accounted for in these partial budgets.

Management of SDI systems is not necessarily more difficult than other irrigation systems, but it does require a different set of management procedures.

Crop Income and Expenses

The crop enterprises for the center pivot cropping system will be irrigated corn with dryland wheat-fallow on the nonirrigated corners. The SDI cropping system area will be in irrigated corn. The irrigation well capacity is assumed adequate for production of irrigated corn in all scenarios. Net revenue from the irrigated areas are projected assuming a corn yield of 190 bushels per acre, a price of $2.50 per bushel, average annual production flexibility contract (PFC) payments of $35 per acre, and production costs based on 1996

K-State Farm Management Guides. The net revenue from nonirrigated wheat acres is based on 40 bushel per acre yields, a price of $3.65 per bushel, PFC payments of $10 per acre, and 1996 K-State production cost estimates.

Because land costs and management expenses over and above base labor expenses are not accounted for in these partial budgets, the net revenue projections represent per-acre net returns to land and management for each irrigated cropping system.

Table 2 reflects the income and Table 3 shows line-by-line variable and fixed expenses for the baseline comparison of the quarter section field (160 acres). In this analysis, SDI systems were assumed to have slightly less irrigation fuel and repair expenses due to lower pumping requirements.

Center pivot irrigated corn was assumed to require 18 inches of applied water while SDI-irrigated corn was assumed to require 16 inches. Large differences exist in irrigation equipment depreciation and interest costs between alternative irrigation systems (Table 3).

Crop production expenses do not vary on a per-acre basis with changes in field size. Similarly, irrigation

equipment depreciation and interest costs do not vary appreciably with field size for SDI on a per-acre basis. However, drastic increases occur in irrigation equipment depreciation and interest costs on a per-acre basis as field size decreases for center pivot systems. Table 4 summarizes these cost and return differences for all the field size scenarios for both SDI and center pivot systems.

Projected center pivot cropping system income and expenses are less than for SDI cropping systems for all field-size scenarios. However, the differences in net returns (income minus expenses) for the two systems vary on a scenario-by-scenario basis. Center pivot systems have a $17 to $23 net returns advantage for larger fields (95 to 160 acres).

Returns for the two systems are essentially the same for the 64-acre scenario, but clearly favor SDI for smaller fields (32 acres). In comparing center pivot wiper and SDI systems on 80-acre tracts, the center pivot wiper cropping system (64 irrigated corn acres plus 16 dryland wheat-fallow acres) retains a small net return advantage ($12 per acre) over the SDI system with 80 acres of irrigated corn.

Table 2. *Crop Revenue Assumptions for SDI and Center Pivot Systems*

Income	Corn (SDI)	Corn (pivot)	Wheat
Crop yield (bu/acre)	190	190	40
Crop price ($/bu)	2.50	2.50	3.65
PFC payment ($/ace)	35	35	10
Total income ($/acre)	510	510	156

2

Sensitivity of Results to Changes in Key Factors

A series of sensitivity analyses were conducted to determine how sensitive these results are to changes in certain key economic factors. These key factors are corn yield and price, irrigation system life, and SDI dripline costs. The sensitivity of projected net returns to these factors was determined for scenarios O (160 acres), D (32 acres), and the wiper scenario (80 acres). These scenarios were selected because they represent the extremes in field size (scenarios O and D) and a difference in center pivot point location and field shape (wiper scenario).

Sensitivity to corn yield and price

Increases in corn yield or price will increase SDI net returns relative to those for the center pivot cropping system (Table 5). The trend is illustrated in Figure 2 for the full size field, scenario O. Figure 2 illustrates that at a corn price of $2.75 per bushel, SDI system net returns are competitive with center pivot cropping systems when corn yields exceed 210 bushels per acre.

The wiper center pivot system remains more profitable in all cases

Table 3. *Corn and Wheat Fallow Expenses and Net Returns for SDI and Center Pivot on a Per-acre Basis for a 160-acre Field (Base Scenario O)*

Cost Items	Cropping System Enterprises

3

except for high yield and price combinations. However, the differences in net returns between the systems are much less for the 80-acre wiper scenario than for the 160-acre full circle (base scenario O). In the small acreage scenario D, SDI has higher net returns in all cases except where both yields and prices are notably below the assumed averages in the preceding analysis.

When corn prices and yields are low, center pivot cropping systems generally have a larger net return advantage. As corn prices and yields increase, SDI systems become more competitive economically.

Sensitivity to irrigation system life

Irrigation system life has a major effect on projected net returns (Table 6). Changes in the life of the SDI system from 5 to 10 to 15 years have a more dramatic effect on net returns than do changes in center pivot system life from 15 to 20 to 25 years.

For example, in base scenario O, the net returns advantage of a center pivot system with a life of 15 years over a SDI system with a life of 10 years is $18 per acre. The net returns advantage of center pivot systems in this scenario increases by $6 per acre to $22 if the center pivot has a 20-year life.

While a change in the life of a center pivot from 15 to 25 years increases projected net returns per acre from $6 to $21 per acre across the three field-size scenarios considered here, an increase in SDI system life from 5 to 15 years increases projected net returns per acre from $71 to $89 per acre, or from at least 3 to 12 times the effect of a 10-year increase in center pivot life.

The effect is most pronounced in scenario D where a change in SDI irrigation system life from 5 to 10 years while holding center pivot system life at 20 years causes a major change in the comparative net returns between the two systems. With a 5-year SDI system life in scenario D, the center pivot system has a $55 per acre net returns advantage over the SDI system.

Conversely, if the SDI system has a 10-year life in this scenario, SDI has an $11 net returns advantage over the

Table 5. *Advantage of Center Pivot Cropping Systems over SDI as Affected by Yield and Price (CP minus SDI Cropping System Returns per Acre)*

Base scenario O: 125 acres center pivot with 35 acres wheat fallow *vs.* 160 acres SDI

	Corn cash prices			
Corn yields (bu/ac)	$2.25/bu	$2.50/bu *	$2.75/bu	$3.00/bu

205	− $ 8	− $19	− $30	− $41
220	− $15	− $27	− $39	− $51

* 190-bushel-per-acre irrigated corn and $2.50 cash price are the standard assumptions in the preceding analysis. The center pivot and SDI systems are assumed to have lives of 20 and 10 years, respectively.

Figure 2. *Net Returns Advantage of a Full-sized 125-acre Center Pivot Cropping System over SDI as Affected by Corn Yield and Price*

center pivot cropping system. SDI systems with a 15-year life clearly have a net returns advantage over center pivot cropping systems with a 25-year life for the wiper and 32-acre scenarios while net returns are nearly equal for the 160-acre scenario (Figure 3).

SDI must have a system life approaching at least 10 years to be economically competitive with center pivot irrigation systems. Research SDI systems at K-State experiment stations have been in use for up to 9 years without any appreciable deterioration.

Several commercial SDI systems in the southwestern United States have been in use for nearly 20 years. Evidence suggests that SDI systems with proper design and management should have good longevity.

Sensitivity to SDI dripline price

Dripline prices have a major effect on the total cost of SDI irrigation systems. Decreasing dripline prices increases the economic competitiveness of SDI. However, the selection of the most profitable irrigation system is not affected within the ranges of

dripline prices and field-size scenarios considered (Figure 4).

The center pivot system remained the most profitable system for scenario O and the wiper system across the range of dripline prices considered. Conversely, for scenario D the SDI cropping system remains the most profitable system across the range of dripline prices considered except at the highest dripline price.

Conclusions

Several factors influence the relative profitability of center pivot and SDI cropping systems. According to the assumptions used in this analysis, center pivot cropping systems have higher estimated net returns than SDI cropping systems on standard quarter-section fields (160 acres).

As field size decreases, center pivot cropping system net returns eventually fall below those of SDI cropping systems. This occurs primarily because per acre investment costs for SDI remain relatively stable as field size declines, whereas a center pivot irrigation system's per-acre investment costs increase markedly.

SDI cropping system net returns are very sensitive to system longevity or life span. If a SDI system only lasts 5 years, it is noncompetitive in a net returns sense with center pivot cropping systems across all field-size scenarios. A SDI system with a 15-year life is economically competitive with center pivots on fields of less than full size (less than 160 acres) and even approaches economic competitiveness on full size fields.

Changes in corn yields and prices have a major effect on the projected net returns of these alternative cropping systems. Higher corn yields and prices favor fully irrigated SDI cropping systems. In this analysis, corn yield and price changes generally do not affect the choice of irrigation systems across the different field-size scenarios for the range of corn yield and prices considered.

Any decrease in dripline prices results in improved SDI net returns relative to center pivot cropping systems. Still though, the selection of the most profitable irrigation and cropping system was not affected

Table 6. *Advantage of Center Pivot Cropping Systems over SDI as Affected by System Life (CP minus SDI Cropping System Returns per Acre)*

Base scenario O: 125 acres center pivot with 35 acres wheat fallow *vs.* 160 acres SDI

Figure 4. *Net Returns Advantage of a Center Pivot Cropping System over SDI as Affected by System Size and SDI Dripline Price*

across the range of dripline prices or cropping system scenarios considered.

The results of this study are highly dependent on the assumptions made in calculating cropping system net returns for western Kansas. Producers considering an investment in either a center pivot or SDI cropping system should complete a partial budget analysis using information specific to their farm. These economic sensitivity analyses were performed by varying only one factor at a time. In practice, several factors may change simultaneously in a farm operation when a center pivot or SDI irrigation system investment is made. If these potential simultaneous factor changes are considered together, the relative profitability results may vary dramatically.

Future SDI applied Research and Extension efforts should focus on several areas. First, there is a need for more information on the longevity of SDI irrigation systems and on the costs of renovating them.

Second, the potential water use efficiencies and uniform application benefits for SDI irrigation systems relative to center pivot irrigation systems needs further investigation.

Third, the income tax management implications of alternative center pivot and SDI investments need to be accounted for in investment decisions. Because of higher system costs and associated tax deductions, SDI system investments would be expected to have an income tax management advantage over center pivot investments for comparable tracts of farmland.

Fourth, an analysis is needed of how increased production risk and lower projected income for nonirrigated crop production influences a crop producer's willingness to select irrigation systems that provide higher proportions of irrigated production for a given piece of farmland. From a farm financial management perspective, potential implications of placing a center pivot or an SDI system on a furrow-irrigated field may have land valuation and tax management effects that should be understood.

Finally, ongoing efforts are needed in the design and development of efficient, low-cost center pivot and SDI irrigation and cropping systems.

Profitability Analysis

Partial budgeting was used to compare the profitability of the alternative irrigation and cropping systems. Unlike a whole-farm budget, a partial budget does not indicate whether the entire operation is profitable, but only if one enterprise or investment has a net returns advantage over another.

Partial budgeting may not recognize all costs to the whole farm. For example, management of newly installed SDI systems may take more time than for the more familiar center pivot systems. The extra time is taken from other farm enterprises, which could affect their production efficiency and profitability. This is a SDI cost factor not accounted for in these partial budgets.

Management of SDI systems is not necessarily more difficult than other irrigation systems, but it does require a different set of management procedures.

Crop Income and Expenses

The crop enterprises for the center pivot cropping system will be irrigated corn with dryland wheat-fallow on the nonirrigated corners. The SDI cropping system area will be in irrigated corn. The irrigation well capacity is assumed adequate for production of irrigated corn in all scenarios. Net revenue from the irrigated areas are projected assuming a corn yield of 190 bushels per acre, a price of $2.50 per bushel, average annual production flexibility contract (PFC) payments of $35 per acre, and production costs based on 1996

K-State Farm Management Guides. The net revenue from nonirrigated wheat acres is based on 40 bushel per acre yields, a price of $3.65 per bushel, PFC payments of $10 per acre, and 1996 K-State production cost estimates.

Because land costs and management expenses over and above base labor expenses are not accounted for in these partial budgets, the net revenue projections represent per-acre net returns to land and management for each irrigated cropping system.

Table 2 reflects the income and Table 3 shows line-by-line variable and fixed expenses for the baseline comparison of the quarter section field (160 acres). In this analysis, SDI systems were assumed to have slightly less irrigation fuel and repair expenses due to lower pumping requirements.

Center pivot irrigated corn was assumed to require 18 inches of applied water while SDI-irrigated corn was assumed to require 16 inches. Large differences exist in irrigation equipment depreciation and interest costs between alternative irrigation systems (Table 3).

Crop production expenses do not vary on a per-acre basis with changes in field size. Similarly, irrigation

equipment depreciation and interest costs do not vary appreciably with field size for SDI on a per-acre basis. However, drastic increases occur in irrigation equipment depreciation and interest costs on a per-acre basis as field size decreases for center pivot systems. Table 4 summarizes these cost and return differences for all the field size scenarios for both SDI and center pivot systems.

Projected center pivot cropping system income and expenses are less than for SDI cropping systems for all field-size scenarios. However, the differences in net returns (income minus expenses) for the two systems vary on a scenario-by-scenario basis. Center pivot systems have a $17 to $23 net returns advantage for larger fields (95 to 160 acres).

Returns for the two systems are essentially the same for the 64-acre scenario, but clearly favor SDI for smaller fields (32 acres). In comparing center pivot wiper and SDI systems on 80-acre tracts, the center pivot wiper cropping system (64 irrigated corn acres plus 16 dryland wheat-fallow acres) retains a small net return advantage ($12 per acre) over the SDI system with 80 acres of irrigated corn.

Table 2. Crop Revenue Assumptions for SDI and Center Pivot Systems

Income	Corn (SDI)	Corn (pivot)	Wheat
Crop yield (bu/acre)	190	190	40
Crop price ($/bu)	2.50	2.50	3.65
PFC payment ($/ace)	35	35	10
Total income ($/acre)	510	510	156

Sensitivity of Results to Changes in Key Factors

A series of sensitivity analyses were conducted to determine how sensitive these results are to changes in certain key economic factors. These key factors are corn yield and price, irrigation system life, and SDI dripline costs. The sensitivity of projected net returns to these factors was determined for scenarios O (160 acres), D (32 acres), and the wiper scenario (80 acres). These scenarios were selected because they represent the extremes in field size (scenarios O and D) and a difference in center pivot point location and field shape (wiper scenario).

Sensitivity to corn yield and price

Increases in corn yield or price will increase SDI net returns relative to those for the center pivot cropping system (Table 5). The trend is illustrated in Figure 2 for the full size field, scenario O. Figure 2 illustrates that at a corn price of $2.75 per bushel, SDI system net returns are competitive with center pivot crop-ping systems when corn yields exceed 210 bushels per acre.

The wiper center pivot system remains more profitable in all cases

Table 3. *Corn and Wheat Fallow Expenses and Net Returns for SDI and Center Pivot on a Per-acre Basis for a 160-acre Field (Base Scenario O)*

Cost Items	Cropping System Enterprises		
	Corn (SDI)	Corn (pivot)	Wheat
Variable costs:			
Labor	$21.15	$21.15	$10.80

3

except for high yield and price combinations. However, the differences in net returns between the systems are much less for the 80-acre wiper scenario than for the 160-acre full circle (base scenario O). In the small acreage scenario D, SDI has higher net returns in all cases except where both yields and prices are notably below the assumed averages in the preceding analysis.

When corn prices and yields are low, center pivot cropping systems generally have a larger net return advantage. As corn prices and yields increase, SDI systems become more competitive economically.

Sensitivity to irrigation system life

Irrigation system life has a major effect on projected net returns (Table 6). Changes in the life of the SDI system from 5 to 10 to 15 years have a more dramatic effect on net returns than do changes in center pivot system life from 15 to 20 to 25 years.

For example, in base scenario O, the net returns advantage of a center pivot system with a life of 15 years over a SDI system with a life of 10 years is $18 per acre. The net returns advantage of center pivot systems in this scenario increases by $6 per acre to $22 if the center pivot has a 20-year life.

While a change in the life of a center pivot from 15 to 25 years increases projected net returns per acre from $6 to $21 per acre across the three field-size scenarios considered here, an increase in SDI system life from 5 to 15 years increases projected net returns per acre from $71 to $89 per acre, or from at least 3 to 12 times the effect of a 10-year increase in center pivot life.

The effect is most pronounced in scenario D where a change in SDI irrigation system life from 5 to 10 years while holding center pivot system life at 20 years causes a major change in the comparative net returns between the two systems. With a 5-year SDI system life in scenario D, the center pivot system has a $55 per acre net returns advantage over the SDI system.

Conversely, if the SDI system has a 10-year life in this scenario, SDI has an $11 net returns advantage over the

Table 5. *Advantage of Center Pivot Cropping Systems over SDI as Affected by Yield and Price (CP minus SDI Cropping System Returns per Acre)*
Base scenario O: 125 acres center pivot with 35 acres wheat fallow *vs.* 160 acres SDI

	Corn cash prices			
Corn yields (bu/ac)	$2.25/bu	$2.50/bu *	$2.75/bu	$3.00/bu
160	$47	$38	$29	$20
175	$39	$30	$20	$11
190 *	$32	$22 *	$12	$ 1
205	$25	$14	$ 3	– $18
220	$18	$ 6	– $ 6	– $18

"Wiper" scenario: 64 acres center pivot with 16 acres wheat fallow *vs.* 80 acres SDI

	Corn cash prices			
Corn yields (bu/ac)	$2.25/bu	$2.50/bu *	$2.75/bu	$3.00/bu
160	$34	$26	$18	$10
175	$28	$19	$10	$ 1
190 *	$21	$12 *	$ 2	– $ 7
205	$15	$ 4	– $ 6	– $16
220	$ 8	– $ 3	– $14	– $25

Scenario D: 25 acres center pivot with 7 acres wheat fallow *vs.* 32 acres SDI

	Corn cash prices			
Corn yields (bu/ac)	$2.25/bu	$2.50/bu *	$2.75/bu	$3.00/bu
160	$13	$ 5	– $ 4	– $13
175	$ 6	– $ 3	– $13	– $22
190 *	– $ 1	– $11 *	– $21	– $32
205	– $ 8	– $19	– $30	– $41
220	– $15	– $27	– $39	– $51

* 190-bushel-per-acre irrigated corn and $2.50 cash price are the standard assumptions in the preceding analysis. The center pivot and SDI systems are assumed to have lives of 20 and 10 years, respectively.

Figure 2. *Net Returns Advantage of a Full-sized 125-acre Center Pivot Cropping System over SDI as Affected by Corn Yield and Price*

center pivot cropping system. SDI systems with a 15-year life clearly have a net returns advantage over center pivot cropping systems with a 25-year life for the wiper and 32-acre scenarios while net returns are nearly equal for the 160-acre scenario (Figure 3).

SDI must have a system life approaching at least 10 years to be economically competitive with center pivot irrigation systems. Research SDI systems at K-State experiment stations have been in use for up to 9 years without any appreciable deterioration.

Several commercial SDI systems in the southwestern United States have been in use for nearly 20 years. Evidence suggests that SDI systems with proper design and management should have good longevity.

Sensitivity to SDI dripline price

Dripline prices have a major effect on the total cost of SDI irrigation systems. Decreasing dripline prices increases the economic competitiveness of SDI. However, the selection of the most profitable irrigation system is not affected within the ranges of

dripline prices and field-size scenarios considered (Figure 4).

The center pivot system remained the most profitable system for scenario O and the wiper system across the range of dripline prices considered. Conversely, for scenario D the SDI cropping system remains the most profitable system across the range of dripline prices considered except at the highest dripline price.

Conclusions

Several factors influence the relative profitability of center pivot and SDI cropping systems. According to the assumptions used in this analysis, center pivot cropping systems have higher estimated net returns than SDI cropping systems on standard quarter-section fields (160 acres).

As field size decreases, center pivot cropping system net returns eventually fall below those of SDI cropping systems. This occurs primarily because per acre investment costs for SDI remain relatively stable as field size declines, whereas a center pivot irrigation system's per-acre investment costs increase markedly.

SDI cropping system net returns are very sensitive to system longevity or life span. If a SDI system only lasts 5 years, it is noncompetitive in a net returns sense with center pivot cropping systems across all field-size scenarios. A SDI system with a 15-year life is economically competitive with center pivots on fields of less than full size (less than 160 acres) and even approaches economic competitiveness on full size fields.

Changes in corn yields and prices have a major effect on the projected net returns of these alternative cropping systems. Higher corn yields and prices favor fully irrigated SDI cropping systems. In this analysis, corn yield and price changes generally do not affect the choice of irrigation systems across the different field-size scenarios for the range of corn yield and prices considered.

Any decrease in dripline prices results in improved SDI net returns relative to center pivot cropping systems. Still though, the selection of the most profitable irrigation and cropping system was not affected

Table 6. *Advantage of Center Pivot Cropping Systems over SDI as Affected by System Life (CP minus SDI Cropping System Returns per Acre)*

Base scenario O: 125 acres center pivot with 35 acres wheat fallow *vs.* 160 acres SDI

	Center pivot life		
SDI system life	15 years	20 years *	25 years
5 years	$72	$76	$78
10 years *	$18	$22 *	$25
15 years	$ 0	$ 4	$ 7
20 years	– $ 9	– $ 5	– $ 2

"Wiper" scenario: 64 acres center pivot with 16 acres wheat fallow *vs.* 80 acres SDI

SDI system life	15 years	20 years *	25 years
5 years	$62	$69	$73
10 years *	$ 5	$12 *	$16
15 years	– $14	– $ 7	– $ 3
20 years	– $24	– $17	– $13

Scenario D: 25 acres center pivot with 7 acres wheat fallow *vs.* 32 acres SDI

SDI system life	15 years	20 years *	25 years
5 years	$43	$55	$63
10 years *	– $24	– $11 *	– $ 3
15 years	– $46	– $33	– $26
20 years	– $57	– $44	– $37

* 20-year center pivot life and 10-year SDI system life are standard assumptions in the preceding analysis. The corn yield is assumed to be 190 bushels per acre with a cash price of $2.50 per bushel.

Figure 3. *Net Returns Advantage of a Center Pivot Cropping System over SDI as Affected by System Size and SDI System Life*

Figure 4. *Net Returns Advantage of a Center Pivot Cropping System over SDI as Affected by System Size and SDI Dripline Price*

across the range of dripline prices or cropping system scenarios considered.

The results of this study are highly dependent on the assumptions made in calculating cropping system net returns for western Kansas. Producers considering an investment in either a center pivot or SDI cropping system should complete a partial budget analysis using information specific to their farm. These economic sensitivity analyses were performed by varying only one factor at a time. In practice, several factors may change simultaneously in a farm operation when a center pivot or SDI irrigation system investment is made. If these potential simultaneous factor changes are considered together, the relative profitability results may vary dramatically.

Future SDI applied Research and Extension efforts should focus on several areas. First, there is a need for more information on the longevity of SDI irrigation systems and on the costs of renovating them.

Second, the potential water use efficiencies and uniform application benefits for SDI irrigation systems relative to center pivot irrigation systems needs further investigation.

Third, the income tax management implications of alternative center pivot and SDI investments need to be accounted for in investment decisions. Because of higher system costs and associated tax deductions, SDI system investments would be expected to have an income tax management advantage over center pivot investments for comparable tracts of farmland.

Fourth, an analysis is needed of how increased production risk and lower projected income for nonirrigated crop production influences a crop producer's willingness to select irrigation systems that provide higher proportions of irrigated production for a given piece of farmland. From a farm financial management perspective, potential implications of placing a center pivot or an SDI system on a furrow-irrigated field may have land valuation and tax management effects that should be understood.

Finally, ongoing efforts are needed in the design and development of efficient, low-cost center pivot and SDI irrigation and cropping systems.
